Theorem (Main result)

SAT and #SAT are fixed-parameter tractable parameterized by the size of a smallest strong backdoor set with respect to the base class of nested CNF formulas.

NESTED-backdoors

SAT and #SAT

SAT

Input: A propositional formula F in conjunctive normal form (CNF)

Question: Is there an assignment to $\text{var}(F)$ satisfying all clauses of F ?

#SAT

Input: A CNF formula F

Question: What is the number of assignment to $\text{var}(F)$ satisfying all clauses of F ?

Example:

$$(x_1 \vee x_2) \wedge (\neg x_2 \vee x_3 \vee \neg x_4) \wedge (x_1 \vee x_4) \wedge (\neg x_1 \vee \neg x_3 \vee \neg x_4)$$

NESTED-backdoors

SAT: theory vs. practice

theory

- NP-complete
- *ETH*: SAT cannot be solved in time $2^{o(n)}$
- *Strong ETH*: SAT cannot be solved in time $(2 - \epsilon)^n$ for any $\epsilon > 0$

practice

- Want to solve an NP-complete problem?
Just encode into SAT and use a SAT solver
- *Real-world* instances with millions of variables and clauses

Backdoors

Parameterized
Complexity

Nested Formulas

Algorithms for
strong
NESTED-backdoors

Backdoors

- Belief: real world instances have a “hidden structure” that makes them easy to solve
- Challenge: measure this hidden structure
- One way: *Backdoor* = set of “key” variables that make it easy to solve the formula

NESTED-backdoors

Backdoors

- CNF formula F
- Set of variables $B \subseteq \text{var}(F)$
- Base class \mathcal{C} : class of poly-time solvable CNF formulas

Definition (Weak Backdoor [Williams, Gomes, Selman, 2003])

B is a **weak \mathcal{C} -backdoor** for F if there is a partial truth assignment τ to B such that $F[\tau] \in \mathcal{C}$ and $F[\tau]$ is satisfiable.

(in $F[\tau]$ all clauses satisfied by τ are removed and the literals on B are removed from all remaining clauses)

Definition (Strong Backdoor [Williams, Gomes, Selman, 2003])

B is a **strong \mathcal{C} -backdoor** for F if for every partial truth assignment τ to B we have $F[\tau] \in \mathcal{C}$.

Parameterized Complexity

Definition (Parameterized problem)

A **parameterized** (decision) problem is a subset of $\Sigma^* \times \mathbb{N}$ for some finite alphabet Σ . For an instance $(x, k) \in \Sigma^* \times \mathbb{N}$, x is the main part and k the parameter.

FPT: class of param. pbs that can be solved in time $f(k) \cdot n^{O(1)}$

W[·]: parameterized **intractability** classes

XP: class of param. pbs that can be solved in time $f(k) \cdot n^{g(k)}$

$$\text{FPT} \subseteq \text{W}[1] \subseteq \text{W}[2] \subseteq \dots \text{XP}.$$

All inclusions believed to be strict.

The classes are closed under parameterized reductions (the parameter of the target problem is upper bounded by a function of the initial parameter).

NESTED-backdoors

Definition

Definition (Nested CNF formula [Knuth, 1990])

A CNF formula is **nested** if its variables can be linearly ordered such that there is no pair of clauses that straddle each other.

A clause c **straddles** a clause c' if there are variables $x, y \in \text{var}(c)$ and $z \in \text{var}(c')$ such that $x < z < y$ in the linear ordering under consideration.

Known Results for Nested Formulas

- Polynomial time algorithm for SAT on nested formulas (linear if the ordering is given)
[Knuth, 1990]
- Nested formulas have incidence treewidth ≤ 3
[Biedl, Henderson, 2004]
- Thus, #SAT can be solved in polynomial time for nested formulas
[Fischer, Makowsky, Ravve, 2008] [Samer, Szeider, 2010]
- A CNF formula F is nested iff the incidence graph of $F + u$ is planar, where u is a new universal clause
[Kratochvíl, Křivánek, 1993]

Backdoor Detection and Evaluation

- Simple detection algorithm
 - for each k -subset B of variables and each assignment τ to B , check whether $F[\tau] \in \text{NESTED}$
 - run time: $\binom{n}{k} \cdot 2^k \cdot n^{O(1)}$
 - **XP**-algorithm
- Simple evaluation algorithm
 - for each assignment τ to B , check whether $F[\tau]$ is satisfiable
 - run time: $2^k \cdot n^{O(1)}$
 - **FPT**-algorithm

FPT-approximation

Theorem

*There is an **FPT** algorithm that either concludes that F has no strong NESTED-backdoor of size at most k or finds a strong NESTED-backdoor of F of size at most 2^k .*

Corollary (Main result)

SAT and #SAT are fixed-parameter tractable parameterized by the size of a smallest strong backdoor set with respect to the base class of nested CNF formulas.

NESTED-backdoors

Outline of the FPT approximation algorithm

- If $\text{inc}(F)$ has “small” treewidth [Bodlaender, 1996]
 - express the problem in MSO_2
 - use Courcelle’s theorem [Courcelle, 1990] [Arnborg, Lagergren, Seese, 1991]
- Otherwise
 - Compute a large grid minor [Robertson, Seymour, 1994] [Kawarabayashi, Kobayashi, Reed, 2012]
 - **Compute a set S^* of $2^{O(k^{10})}$ variables such that every strong NESTED-backdoor contains at least one of these variables**
 - For each $x \in S^*$, recurse on $F[x = 1]$ and $F[x = 0]$ with parameter $k - 1$
 - If, for some $x \in S^*$, both recursive calls return backdoors B_x and $B_{\neg x}$, then return $B_x \cup B_{\neg x} \cup \{x\}$
 - Otherwise, return No

Internal and External Killers

An internal killer

An external killer

There are at most k internal killers.

Look closely at interaction of obstructions and external killers:
Either “sparse” interaction \rightarrow no solution, or
or “dense” interaction \rightarrow new obstructions emerge spanning
external killers and known obstructions, forcing a backdoor to
contain one variable among a few.
